Why should I believe that these screenshots are authentic?

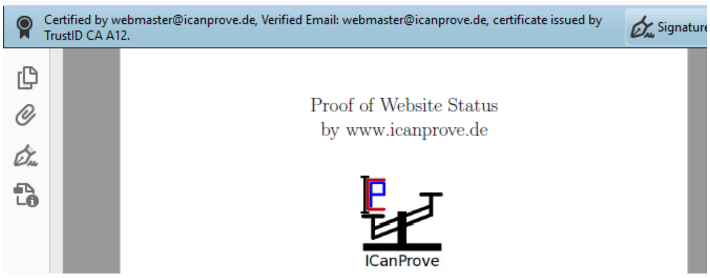
These screenshots have been created by a remote controlled browser that immediately digitally signed this document. After signing the document became immutable so the party that sent you this document had no opportunity to modify them. To verify this you must check, that the embedded signature is valid and belongs to webmaster@icanprove.de. The following sections will guide you through this process.

What is a digitally signed Document?

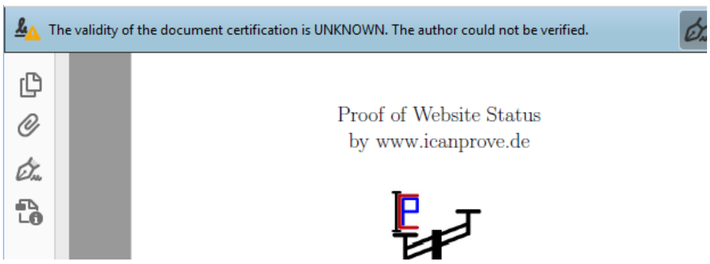
A digitally signed document contains an additional information: A digital signature. This is a mathematical construct so tightly interwoven with the document that it is destroyed if the document is modified. The digital signature is a sequence of numbers that including the name of the signer and a so called hash-value constitutes a solution to a complicated mathematical equation. The hash-value is the result of a mathematical function using all parts of the document as its input. This function has been designed to map small changes of the document to very different values. So modifying any part of the document will change this hash-value invalidating the aforementioned equation. To make this valid again the name of the signer and/or the signature have to be adapted. The equation is so complicated that finding a new adapted signature is so difficult that one needs some secret information (the private key held by the signer) to do so. The certification authorities choose the equations (parametrized the equations) in a way that solving them is virtually impossible without a "secret private key" only held by the authrorized signers. For checking the validity the parameters defining the equation can either be obtained from the signer's website or are included and signed by another party, and so on constituting the so called "chain of trust" that usually ist anchored with an equation built into your operating system, your browser or has been obtained manually.

How do I recognize digitally signed documents ?

Many PDF viewers e.g. AdobeReader® verify and display digital signatures. A PDF-file signed by ICanProve.de looks like the picture to the right:
More Information can be obtained by clicking on the ICanProve logo or choosing the "signatures" tab. You should check that the document is marked as "unchanged" and "LTV enabled". If in doubt have this information checked by an expert for digital signatures and public key infrastructures (PKI).



AdobeReader® reports a digital signature but flags it UNKNOWN.



AdobeReader® can use certificates for digital signatures from different sources. The certificate used by IcanProve.de has not been commissioned by Adobe® but by a different company that cooperates with many operating system vendors. Therefore certificates stored by the operating system have to be applied for verification. To enable these (using Microsoft Windows®) choose Edit - Preferences - Signatures - Verification - More - Windows-Integration and check the two boxes.
